Fear of Walking Outdoors

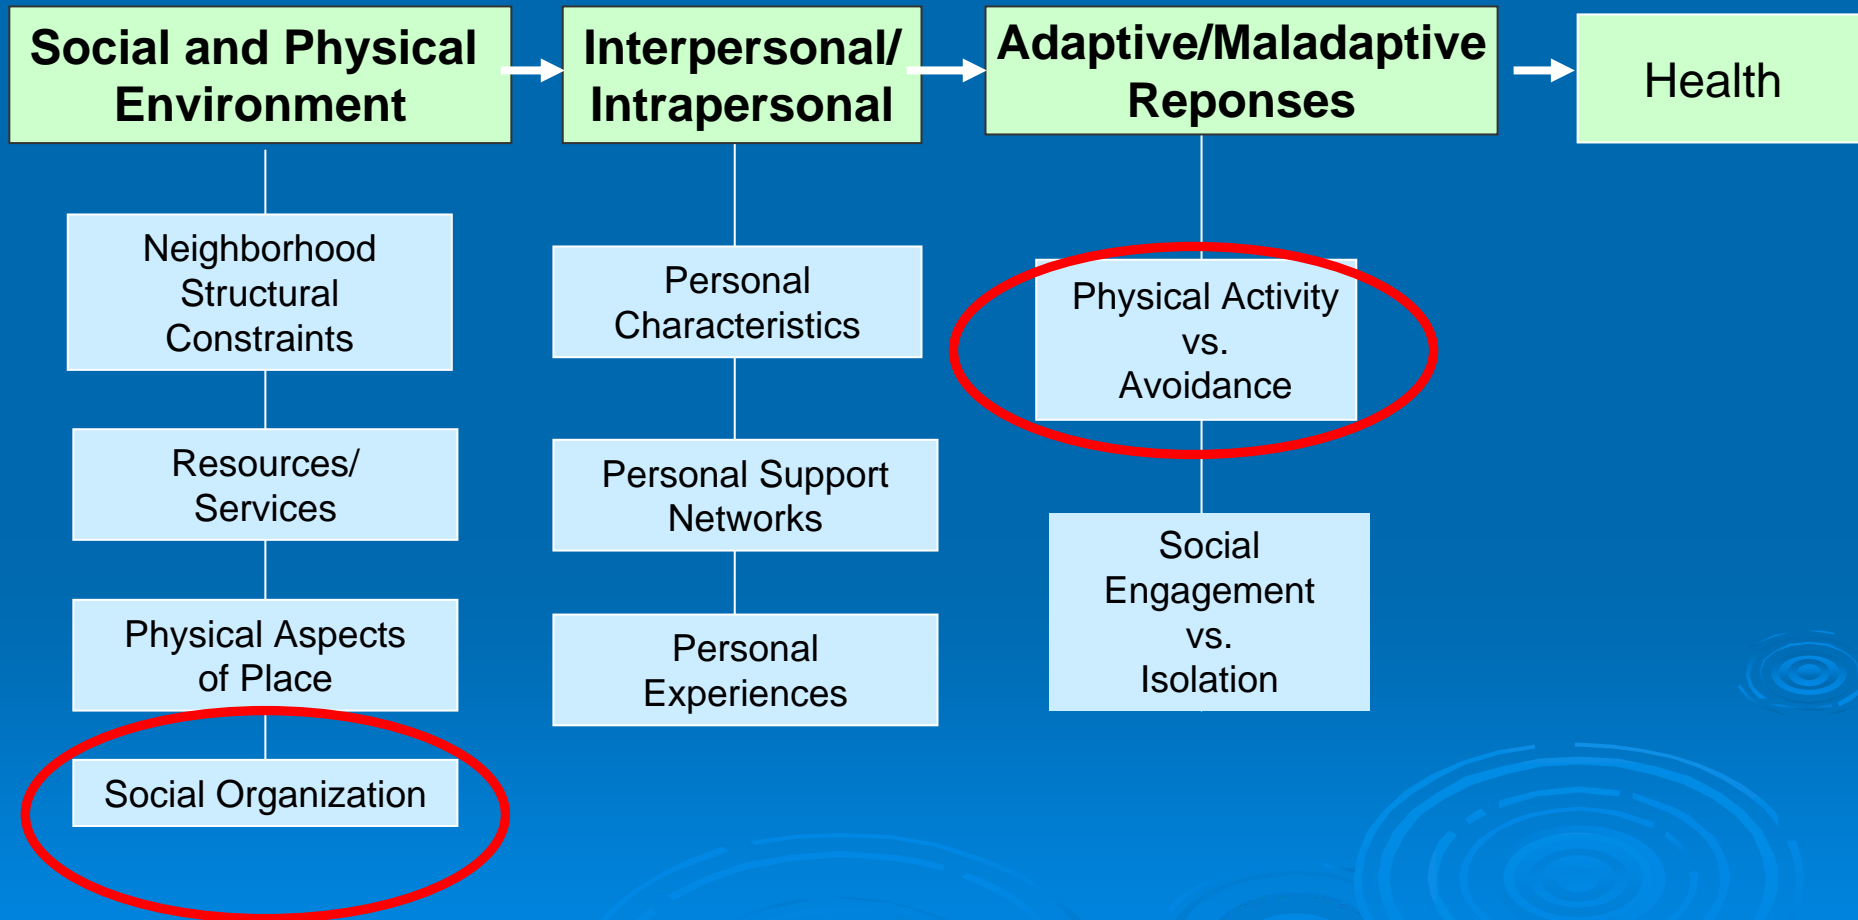

An Ecological Analysis of Violence and Disorder in Urban Neighborhoods

Background

- Proliferation of Socio-Ecological Models
 - Social Networks + Built Environment \longrightarrow Active Living
- Crime and disorder often over-looked
- Poor specification of crime constructs
- Unavailability of measures at low levels of aggregation
- Within criminological literature, behavioral responses to fear of crime not well understood

Socio-Ecological Framework

Focus on Maladaptive Response

- How often does worry about crime prevent you from walking somewhere in your neighborhood?

Key Hypotheses

- Neighborhood levels of violence will be positively associated with fear/avoidance of walking
 - The presence of gangs (social disorder) will be positively associated with fear/avoidance of walking
 - Increased neighborhood cohesion will mediate the impact of violence and gangs on fear/avoidance of walking
- 
- A decorative graphic consisting of several sets of concentric circles in shades of blue, located in the bottom right corner of the slide.

Hypotheses—continued

- Relationships will hold true controlling for individual-level factors, physical environment and social environment
 - Men and women will be differentially affected by the safety of their environment
 - Influence of neighborhood cohesion will vary by race of respondent
- 

Methods

Design: Cross sectional analysis using multi-level models

Data sources:

- In-person neighborhood survey (2005); Stratified random sample of urban residents within 55 Washington D.C. neighborhoods (N=901); Great variation in socio-demographics across neighborhoods
 - Response rate 67%
- Neighborhood-level = block group
- 2000 Census data linked to individual level
- Planning and land use data
- Law enforcement data

Dependent Measure

- How often does worry about crime prevent you from walking somewhere in your neighborhood?
(a) never/rarely (b) sometimes (c) often

Independent Measures (1)

- Age, gender, race (black), percent of lifetime living in same house, friendship/kinship ties
- Crime and disorder:
 - officially reported violent crime (average of 2004-05);
 - law enforcement intelligence data on location and number of gangs
- Physical environment:
 - percent of block group comprised of parkland
 - percent of parcels that are vacant

Independent Measures (2)

- Neighborhood structural constraints:
 - Concentrated disadvantage (poverty, female headed households, unemployment, welfare)
 - residential stability (time in home, homeowner)
 - racial heterogeneity
- Collective efficacy: social cohesion and informal social control

Statistical Analysis

➤ Multi-level Models

- Account for clustering of residents within neighborhoods
- Assess how neighborhood level constructs interact with personal characteristics
- STATA GLLAMM procedure ordered logit--
Estimating the odds of predictors increasing fear one category

Statistical Analysis (2)

➤ Level 1 (Individual)

- Age, gender, race, percent of lifetime living in same house, friendship/kinship ties

➤ Level 2 (Block Group)

- Violent crime; number of gangs
- Percent parkland; percent vacant parcels
- Concentrated disadvantage, residential stability, racial heterogeneity
- Neighborhood collective efficacy/"cohesion"

Statistical Analysis (3)

- Cross-level interactions
 - Gender*levels of violence
 - Race*neighborhood collective efficacy

Results: Avoidance of Walking Outside Due to Fear of Crime

- Significant individual-level variables:
 - Age: Increase in 10 yrs increases odds of moving up a level in fear by 20%
 - Gender: Women twice as likely to be in higher category
 - Time in Neighborhood: 10% increase in time in neighborhood leads to 7% decrease in odds of being in higher level of fear
 - Kinship ($p < .15$)
1 SD increase in kinship ties decreases odds of being in higher level by 11%

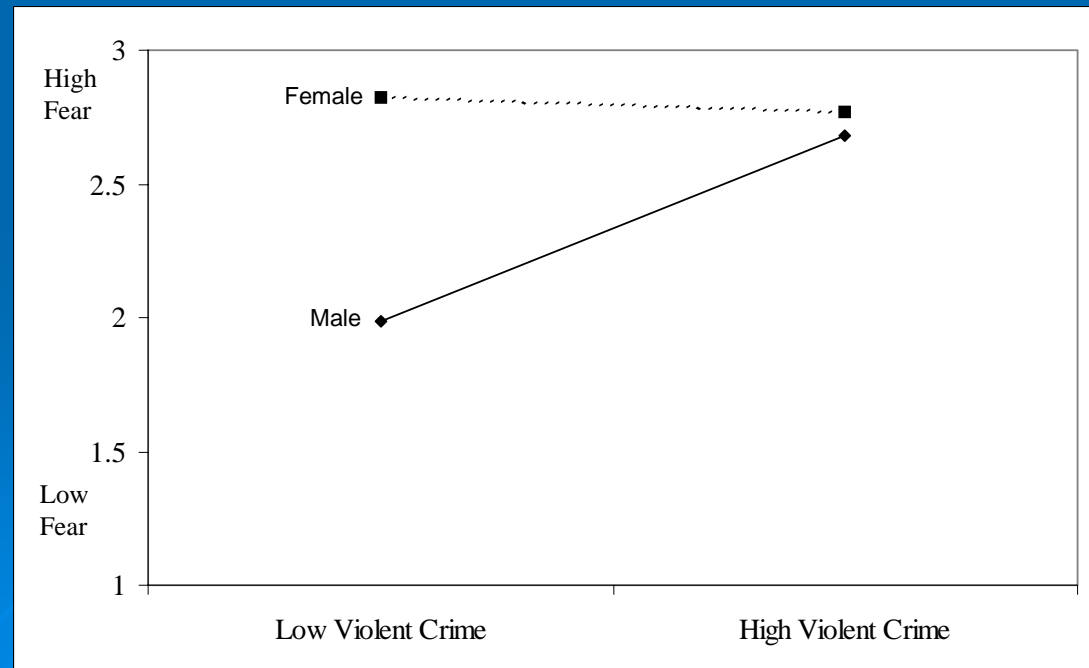

Results: Avoidance of Walking Outside Due to Fear of Crime

- Significant neighborhood-level variables
 - Number of violent crimes:
Addition of 10 violent crimes/year increases odds of moving up a level of fear by 20%
 - Concentrated disadvantage ($p < .15$)
1 SD increase in disadvantage increases the odds of moving up a level of fear by 44%

Results: Avoidance of Walking Outside Due to Fear of Crime

- Cross-level interactions
 - Gender*levels of violence

The effect of levels of violence on fear/avoidance of walking is greater for males than females

Results: Avoidance of Walking Outside Due to Fear of Crime

➤ Cross-level interactions

- Race*neighborhood collective efficacy

Collective efficacy mediates the relationship between residents' fear and levels of violence, but not for Blacks

Limitations

- Cross sectional study
- Generalizability
- New dependent variable
- High correlation between gangs and disadvantage

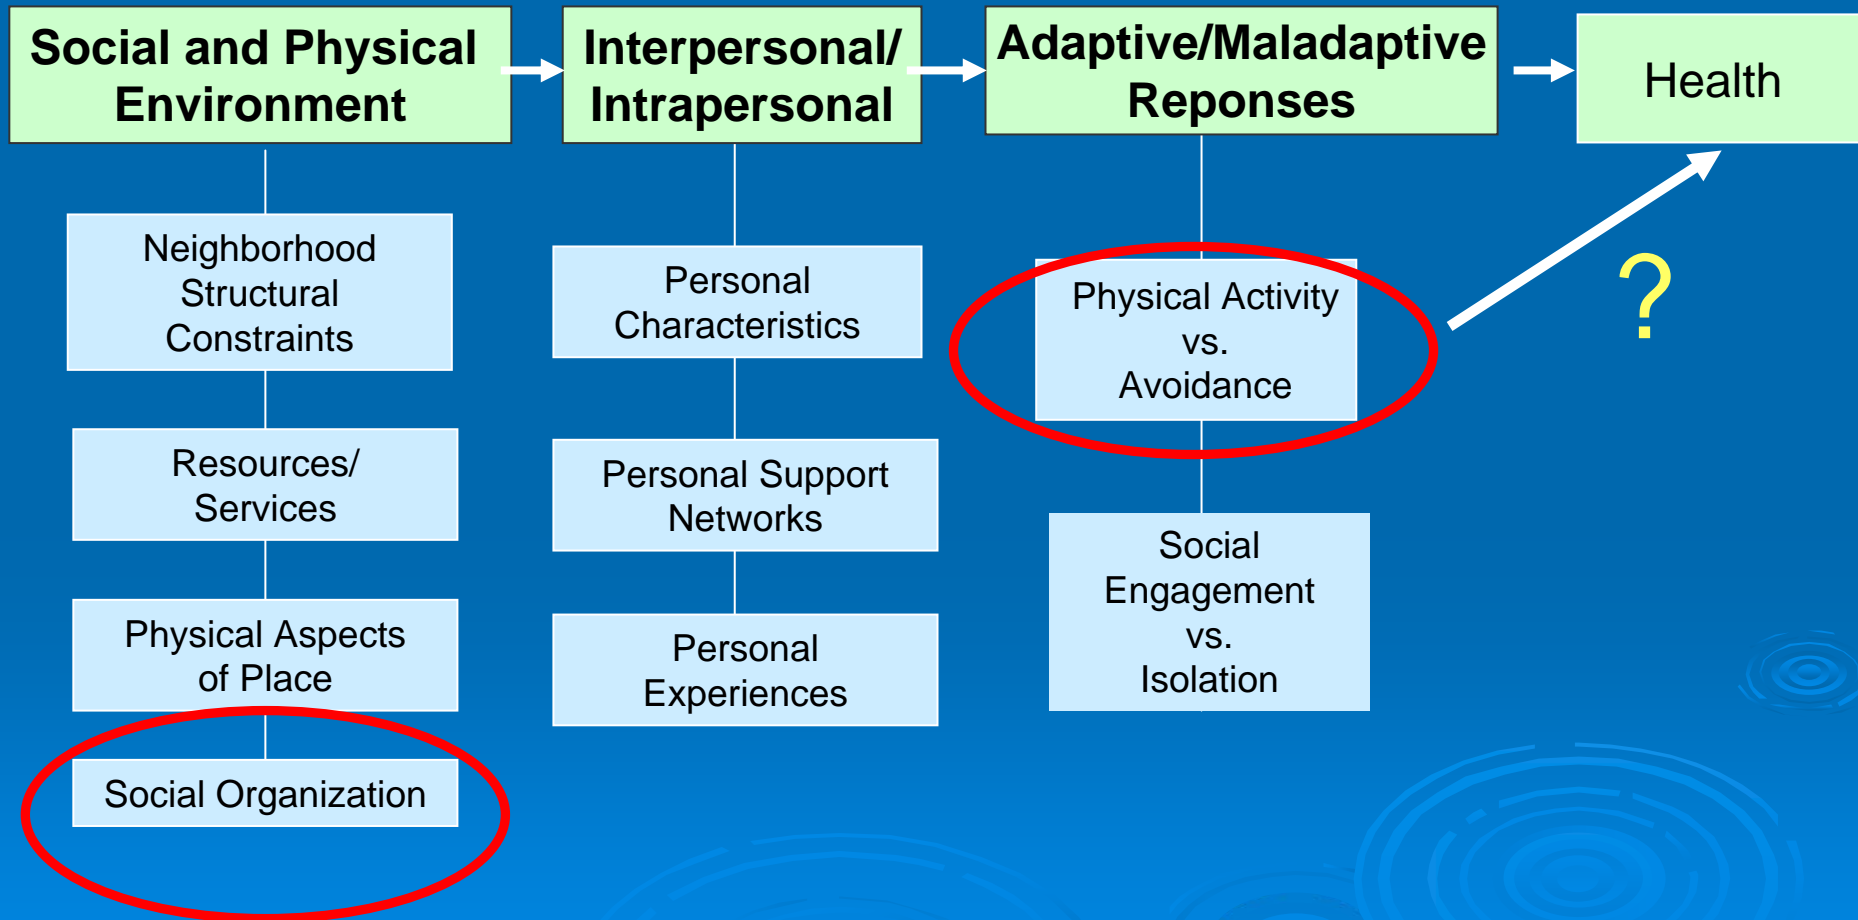

Summary

- Theoretical and empirical progress: Avoidance of walking in neighborhood is maladaptive response to fear
 - Women are fearful, regardless of levels of violence—high levels of violence are associated with avoidance of walking—for males.
 - Collective efficacy can reduce maladaptive response, but effect varies by race
- 

Summary

- Additional research to dissect components of collective efficacy and how/why it interacts with race
 - Violence should be treated as public health issue
 - Strategizing about active living should include consideration of ways to reduce violence
 - Go beyond Crime Prevention through Environmental Design (CPTED).
- 

Next Steps: Close the Gap
